 Bollen

Bollen's Data on Industrialization and Political Democracy

Description

This data set includes four measures of democracy at two points in time, 1960 and 1965, and three measures of industrialization in 1960, for 75 developing countries.

Usage

Bollen

Format

A data frame with 75 observations on the following 11 variables.

- y1 freedom of the press, 1960
- y2 freedom of political opposition, 1960
- y3 fairness of elections, 1960
- y4 effectiveness of elected legislature, 1960
- y5 freedom of the press, 1965
- y6 freedom of political opposition, 1965
- y7 fairness of elections, 1965
- y8 effectiveness of elected legislature, 1965
- x1 GNP per capita, 1960
- x2 energy consumption per capita, 1960
- x3 percentage of labor force in industry, 1960

Details

Variables y1 through y4 are intended to be indicators of the latent variable *political democracy in 1960*; y5 through y8 indicators of *political democracy in 1965*; and x1 through x3 indicators of *industrialization in 1960*.

bootSem

Bootstrap a Structural Equation Model

Description

Bootstraps a structural equation model in an sem object (as returned by the [sem](#) function).

Usage

```
bootSem(model, ...)

## S3 method for class 'sem'
bootSem(model, R=100, Cov=cov, data=model$data,
        max.failures=10, show.progress=TRUE, ...)

## S3 method for class 'msem'
bootSem(model, R=100, Cov=cov, data=model$data,
        max.failures=10, show.progress=TRUE, ...)

## S3 method for class 'bootsem'
print(x, digits=getOption("digits"), ...)

## S3 method for class 'bootsem'
summary(object,
        type=c("perc", "bca", "norm", "basic", "none"), level=0.95, ...)
```

Arguments

model	an sem or msem object, produced by the sem function.
R	the number of bootstrap replications; the default is 100, which should be enough for computing standard errors, but not confidence intervals (except for the normal-theory intervals).
Cov	a function to compute the input covariance or moment matrix; the default is cov . Use cor if the model is fit to the correlation matrix. The function hetcor in the polycor package will compute product-moment, polychoric, and polyserial correlations among mixed continuous and ordinal variables (see the first example below for an illustration).
data	in the case of a sem (i.e., single-group) model, a data set in a form suitable for Cov; for example, for the default Cov=cov, data may be a numeric data frame or a numeric matrix. In the case of an msem (i.e., multi-group) model, a list of data sets (again in the appropriate form), one for each group; in this case, bootstrapping is done within each group, treating the groups as strata. Note that the original observations are required, not just the covariance matrix of the observed variables in the model. The default is the data set stored in the sem object, which will be present only if the model was fit to a data set rather than to a covariance or moment matrix, and may not be in a form suitable for Cov.
max.failures	maximum number of consecutive convergence failures before bootSem gives up.
show.progress	display a text progress bar on the console tracing the bootstrap replications.
x, object	an object of class bootsem.
digits	controls the number of digits to print.
type	type of bootstrapped confidence intervals to compute; the default is "perc" (percentile); see boot.ci for details.
level	level for confidence intervals; default is 0.95.
...	in bootSem, arguments to be passed to sem ; otherwise ignored.

Details

bootSem implements the nonparametric bootstrap, assuming an independent random sample. Convergence failures in the bootstrap resamples are discarded (and a warning printed); more than `max.failures` consecutive convergence failures (default, 10) result in an error. You can use the [boot](#) function in the **boot** package for more complex sampling schemes and additional options.

Bootstrapping is implemented by resampling the observations in data, recalculating the input covariance matrix with `Cov`, and refitting the model with `sem`, using the parameter estimates from the original sample as start-values.

Warning: the bootstrapping process can be very time-consuming.

Value

bootSem returns an object of class `bootsem`, which inherits from class `boot`, supported by the **boot** package. The returned object contains the following components:

<code>t0</code>	the estimated parameters in the model fit to the original data set.
<code>t</code>	a matrix containing the bootstrapped estimates, one bootstrap replication per row.
<code>data</code>	the data to which the model was fit.
<code>seed</code>	the value of <code>.Random.seed</code> when bootSem was called.
<code>statistic</code>	the function used to produce the bootstrap replications; this is always the local function <code>refit</code> from bootSem.
<code>sim</code>	always set to "ordinary"; see the documentation for the boot function.
<code>stype</code>	always set to "i"; see the documentation for the boot function.
<code>call</code>	the call of the bootSem function.
<code>weights</code>	a vector of length equal to the number of observations N , with entries $1/N$. For a multi-group model, the weights in group j are $1/N_j$, the inverse of the number of observations in the group.
<code>strata</code>	a vector of length N containing the number of the stratum to which each observation belongs; for a single-group model, all entries are 1.

 CNES

Variables from the 1997 Canadian National Election Study

Description

These variables are from the mailback questionnaire to the 1997 Canadian National Election Study, and are intended to tap attitude towards “traditional values.”

Usage

CNES

Format

A data frame with 1529 observations on the following 4 variables.

MBSA2 an ordered factor with levels StronglyDisagree, Disagree, Agree, and StronglyAgree, in response to the statement, “We should be more tolerant of people who choose to live according to their own standards, even if they are very different from our own.”

MBSA7 an ordered factor with levels StronglyDisagree, Disagree, Agree, and StronglyAgree, in response to the statement, “Newer lifestyles are contributing to the breakdown of our society.”

MBSA8 an ordered factor with levels StronglyDisagree, Disagree, Agree, and StronglyAgree, in response to the statement, “The world is always changing and we should adapt our view of moral behaviour to these changes.”

MBSA9 an ordered factor with levels StronglyDisagree, Disagree, Agree, and StronglyAgree, in response to the statement, “This country would have many fewer problems if there were more emphasis on traditional family values.”

effects.sem

Total, Direct, and Indirect Effects for Structural Equation Models

Description

The sem method for the standard generic function effects computes total, direct, and indirect effects for a fitted structural equation model according to the method described in Fox (1980).

Usage

```
## S3 method for class 'sem'
effects(object, ...)
## S3 method for class 'msem'
effects(object, ...)

## S3 method for class 'semeffects'
print(x, digits = getOption("digits"), ...)
## S3 method for class 'semeffectsList'
print(x, digits = getOption("digits"), ...)
```

Arguments

object	a fitted structural-equation model object produced by the sem function.
x	an object of class semeffects or semeffectsList, produced by effects.
digits	digits to print.
...	not used.

Value

effect.sem returns an object of class semeffects with Total, Direct, and Indirect elements.

```

Description

This data set, for scores on a variety of tests, was originally in the MBESS package. A new version of the data set in that package doesn't appear to be identical to this one.

Usage

HS.data

Format

A data frame with 301 observations on the following 32 variables.

id a numeric vector
Gender a factor with levels Female Male
grade a numeric vector
agey a numeric vector
agem a numeric vector
school a factor with levels Grant-White Pasteur
visual a numeric vector
cubes a numeric vector
paper a numeric vector
flags a numeric vector
general a numeric vector
paragrap a numeric vector
sentence a numeric vector
wordc a numeric vector
wordm a numeric vector
addition a numeric vector
code a numeric vector
counting a numeric vector
straight a numeric vector
wordr a numeric vector
numberr a numeric vector
figurer a numeric vector
object a numeric vector
numberf a numeric vector
figurew a numeric vector
deduct a numeric vector
numeric a numeric vector
problemr a numeric vector
series a numeric vector
arithmet a numeric vector
paperrev a numeric vector
flagssub a numeric vector

Klein

Klein's Data on the U. S. Economy

Description

Data for Klein's (1950) simple econometric model of the U. S. economy.
The Klein data frame has 22 rows and 10 columns.

Usage

Klein

Format

This data frame contains the following columns:

Year 1921–1941

C consumption.

P private profits.

Wp private wages.

I investment.

K.lag capital stock, lagged one year.

X equilibrium demand.

Wg government wages.

G government non-wage spending.

T indirect business taxes and net exports.

  data=Klein))
```

Kmenta

Partly Artificial Data on the U. S. Economy

Description

These are partly contrived data from Kmenta (1986), constructed to illustrate estimation of a simultaneous-equation model.

The Kmenta data frame has 20 rows and 5 columns.

Usage

Kmenta

Format

This data frame contains the following columns:

Q food consumption per capita.

P ratio of food prices to general consumer prices.

D disposable income in constant dollars.

F ratio of preceding year's prices received by farmers to general consumer prices.

A time in years.

Details

The exogenous variables D, F, and A are based on real data; the endogenous variables P and Q were generated by simulation.

Source

Kmenta, J. (1986) *Elements of Econometrics, Second Edition*, Macmillan.

miSem

*Estimate a Structural Equation Model By Multiple Imputation***Description**

miSem uses the `mi` function in the `mi` package to generate multiple imputations of missing data, fitting the specified model to each completed data set.

Usage

```
miSem(model, ...)

## S3 method for class 'semmod'
miSem(model, ..., data, formula = ~., raw=FALSE,
       fixed.x=NULL, objective=objectiveML,
       n.imp=5, n.chains=n.imp, n.iter=30, seed=sample(1e6, 1), mi.args=list(),
       show.progress=TRUE)

## S3 method for class 'semmodList'
miSem(model, ..., data, formula = ~., group, raw=FALSE,
       fixed.x=NULL, objective=msemObjectiveML,
       n.imp=5, n.chains=n.imp, n.iter=30, seed=sample(1e6, 1), mi.args=list(),
       show.progress=TRUE)

## S3 method for class 'miSem'
print(x, ...)

## S3 method for class 'miSem'
summary(object, digits=max(3, getOption("digits") - 2), ...)
```

Arguments

<code>model</code>	an SEM model-description object of class <code>semmod</code> or <code>semmodList</code> , created by specifyEquations <code>cfa</code> , or specifyModel , in the case of a multi-group model in combination with multigroupModel .
<code>..., formula, raw, fixed.x, objective, group</code>	arguments to be passed to sem .
<code>data</code>	an R data frame, presumably with some missing data (encoded as NA), containing the data for fitting the SEM, possibly along with other variables to use to obtain multiple imputations of missing values. In the case of a multi-group model, this must be a <i>single</i> data frame.
<code>n.imp</code>	number of imputations (default 5).
<code>n.chains</code>	number of Markov chains (default is the number of imputations).
<code>n.iter</code>	number of iterations for the multiple-imputation process (default 30).
<code>seed</code>	seed for the random-number generator (default is an integer sampled from 1 to 1E6); stored in the resulting object.

<code>mi.args</code>	other arguments to be passed to <code>mi</code> .
<code>show.progress</code>	show a text progress bar on the console tracking model fitting to the multiple imputations; this is distinct from the progress of the multiple-imputation process, which is controlled by the <code>verbose</code> argument to <code>mi</code> (and which, although it defaults to TRUE, <i>fails</i> to produce verbose output on Windows system, as of <code>mi</code> version 1.0).
<code>x, object</code>	an object of class "miSem".
<code>digits</code>	for printing numbers.

Value

`miSem` returns an object of class "miSem" with the following components:

<code>initial.fit</code>	an sem model object produced using <code>objectiveFIML</code> if <code>raw=TRUE</code> , or the objective function given by the <code>objective</code> argument otherwise.
<code>mi.fits</code>	a list of sem model objects, one for each imputed data set.
<code>imputation</code>	the object produced by <code>complete</code> , containing the completed imputed data sets.
<code>seed</code>	the seed used for the random number generator.
<code>mi.data</code>	the object returned by <code>mi</code> , containing the multiple imputations, and useful, e.g., for diagnostic checking of the imputation process.

ML.methods	<i>Methods for sem Objects Fit Using the objectiveML, objectiveGLS, objectiveFIML, msemObjectiveML, and msemObjectiveGLS Objective Functions</i>
------------	--

Description

These functions are for objects fit by `sem` using the `objectiveML` (multivariate-normal full-information maximum-likelihood), `link{objectiveFIML}` (multivariate-normal full-information maximum-likelihood in the presence of missing data), `objectiveGLS` (generalized least squares), and `msemObjectiveML` (multigroup multivariate-normal FIML) objective functions.

Usage

```

## S3 method for class 'objectiveML'
anova(object, model.2, robust=FALSE, ...)
## S3 method for class 'objectiveFIML'
anova(object, model.2, ...)

## S3 method for class 'objectiveML'
logLik(object, ...)
## S3 method for class 'objectiveFIML'
logLik(object, saturated=FALSE,
  intercept="Intercept", iterlim=1000, ...)
## S3 method for class 'objectiveML'
deviance(object, ...)
## S3 method for class 'objectiveFIML'
deviance(object, saturated.logLik, ...)
## S3 method for class 'msemObjectiveML'
deviance(object, ...)

```

```

## S3 method for class 'objectiveML'
AIC(object, ..., k)
## S3 method for class 'objectiveFIML'
AIC(object, saturated.logLik, ..., k)
## S3 method for class 'msemObjectiveML'
AIC(object, ..., k)
## S3 method for class 'objectiveML'
AICc(object, ...)
## S3 method for class 'objectiveFIML'
AICc(object, saturated.logLik, ...)
## S3 method for class 'msemObjectiveML'
AICc(object, ...)
## S3 method for class 'objectiveML'
BIC(object, ...)
## S3 method for class 'objectiveFIML'
BIC(object, saturated.logLik, ...)
## S3 method for class 'msemObjectiveML'
BIC(object, ...)
## S3 method for class 'objectiveML'
CAIC(object, ...)
## S3 method for class 'objectiveFIML'
CAIC(object, saturated.logLik, ...)

## S3 method for class 'objectiveML'
print(x, ...)
## S3 method for class 'objectiveGLS'
print(x, ...)
## S3 method for class 'objectiveFIML'
print(x, saturated=FALSE, ...)
## S3 method for class 'msemObjectiveML'
print(x, ...)
## S3 method for class 'msemObjectiveGLS'
print(x, ...)

## S3 method for class 'objectiveML'
summary(object, digits=getOption("digits"),
         conf.level=.90, robust=FALSE, analytic.se=object$t <= 500,
         fit.indices=c("GFI", "AGFI", "RMSEA", "NFI", "NNFI", "CFI", "RNI",
                       "IFI", "SRMR", "AIC", "AICc", "BIC", "CAIC"), ...)
## S3 method for class 'objectiveFIML'

        analytic.se=object$ t <= 500,
        fit.indices=c("GFI", "AGFI", "RMSEA", "NFI", "NNFI", "CFI", "RNI",
                      "IFI", "SRMR", "AIC", "AICc", "BIC"), ...)
## S3 method for class 'msemObjectiveGLS'
summary(object, digits=getOption("digits"),
        conf.level=.90,
        fit.indices=c("GFI", "AGFI", "RMSEA", "NFI", "NNFI",
                      "CFI", "RNI", "IFI", "SRMR"), ...)
```

Arguments

object, model.2, x	an object inheriting from class objectiveML, objectiveGLS, objectiveFIML, msemObjectiveML, or msemObjectiveGLS.
robust	if TRUE, compute robust standard errors or test.
fit.indices	a character vector of “fit indices” to report; the allowable values are those given in Usage above, and vary by the objective function. If the argument isn’t given then the fit indices reported are taken from the R fit.indices option; if this option isn’t set, then only the AIC and BIC are reported for models fit with objectiveML, objectiveFIML, or msemObjectiveML, and no fit indices are reported for models fit with objectiveGLS or msemObjectiveGLS.
k, ...	ignored.
digits	digits to be printed.
conf.level	level for confidence interval for the RMSEA index (default is .9).
analytic.se	use analytic (as opposed to numeric) coefficient standard errors; default is TRUE where analytic standard errors are available if there are no more than 100 parameters in the model and FALSE otherwise.
saturated	if TRUE (the default is FALSE); compute the log-likelihood (and statistics that depend on it) for the saturated model when the objective function is FIML in the presence of missing data. This can be computationally costly.
intercept	the name of the intercept regressor in the raw data, to be used in calculating the saturated log-likelihood for the FIML estimator; the default is "Intercept".
saturated.logLik	the log-likelihood for the saturated model, as returned by logLik with saturated=TRUE; if absent, this will be computed and the computation can be time-consuming.
iterlim	iteration limit used by the nlm optimizer to compute the saturated log-likelihood for the FIML estimator with missing data; defaults to 1000.

 modIndices

Modification Indices for Structural Equation Models

Description

mod.indices calculates modification indices (score tests) and estimated parameter changes for the fixed and constrained parameters in a structural equation model fit by multinormal maximum likelihood.

Usage

```
## S3 method for class 'objectiveML'
modIndices(model, duplicated, deviance=NULL, ...)
## S3 method for class 'msemObjectiveML'
modIndices(model, ...)

## S3 method for class 'modIndices'
print(x, n.largest=5, ...)
## S3 method for class 'msemModIndices'
print(x, ...)

## S3 method for class 'modIndices'
summary(object, round=2,
         print.matrices=c("both", "par.change", "mod.indices"), ...)
## S3 method for class 'msemModIndices'
summary(object, ...)
```

Arguments

model	an object of class objectiveML or msemObjectiveML, produced by the sem function.
object, x	an object of class modIndices or msemModIndices, produced by the modIndices function.
n.largest	number of modification indices to print in each of the A and P matrices of the RAM model.
round	number of places to the right of the decimal point in printing modification indices.
print.matrices	which matrices to print: estimated changes in the fixed parameters, modification indices, or both (the default).
duplicated, deviance	for internal use.
...	arguments to be passed down.

Details

Modification indices are one-df chi-square score (“Lagrange-multiplier”) test statistics for the fixed and constrained parameters in a structural equation model. They may be regarded as an estimate of the improvement in the likelihood-ratio chi-square statistic for the model if the corresponding parameter is respecified as a free parameter. The `modIndices` function also estimates the change in the value of a fixed or constrained parameter if the parameter is respecified as free. When several parameters are set equal, modification indices and estimated changes are given for all but the first. Modification indices and estimated parameter changes for currently free parameters are given as NA. The method employed is described in Saris, Satorra, and Sorbom (1987) and Sorbom (1989).

Value

`modIndices` returns an object of class `modIndices` with the following elements:

<code>mod.A</code>	modification indices for the elements of the A matrix.
<code>mod.P</code>	modification indices for the elements of the P matrix.
<code>par.A</code>	estimated parameter changes for the elements of the A matrix.
<code>par.P</code>	estimated parameter changes for the elements of the P matrix.

objective.functions *sem Objective-Function Builders*

Description

These functions return objective functions suitable for use with [optimizers](#) called by [sem](#). The user would not normally call these functions directly, but rather supply one of them in the `objective` argument to `sem`. Users may also write their own objective functions. `objectiveML` and `objectiveML2` are for multinormal maximum-likelihood estimation; `objectiveGLS` and `objectiveGLS2` are for

generalized least squares; and `objectiveFIML2` is for so-called “full-information maximum-likelihood” estimation in the presence of missing data. The FIML estimator provides the same estimates as the ML estimator when there is no missing data; it can be slow because it iterates over the unique patterns of missing data that occur in the data set. `objectiveML` and `objectiveGLS` use compiled code and are therefore substantially faster. `objectiveML2` and `objectiveGLS2` are provided primarily to illustrate how to write sem objective functions in R. `msemObjectiveML` uses compiled code is for fitting multi-group models by multinormal maximum likelihood; `msemObjectiveML2` is similar but doesn’t use compiled code. `msemObjectiveGLS` uses compiled code and is for fitting multi-group models by generalized least squares.

Usage

```
objectiveML(gradient=TRUE, hessian=FALSE)
objectiveML2(gradient=TRUE)

objectiveGLS(gradient=FALSE)
objectiveGLS2(gradient=FALSE)

objectiveFIML(gradient=TRUE, hessian=FALSE)
objectiveFIML2(gradient=TRUE, hessian=FALSE)

msemObjectiveML(gradient=TRUE)
msemObjectiveML2(gradient=TRUE)

msemObjectiveGLS(gradient=FALSE)
```

Arguments

<code>gradient</code>	If TRUE, the object that’s returned includes a function for computing an analytic gradient; there is at present no analytic gradient available for <code>objectiveFIML</code> , <code>objectiveGLS</code> , <code>objectiveGLS2</code> , or <code>msemObjectiveGL</code> .
<code>hessian</code>	If TRUE, the object returned includes a function to compute an analytic Hessian; only available for <code>objectiveML</code> and not generally recommended.

Value

These functions return an object of class “`semObjective`”, with up to two elements:

<code>objective</code>	an objective function.
<code>gradient</code>	a gradient function.

optimizers

sem Optimizers

Description

The default optimizer used by `sem` is `optimizerSem`, which employs compiled code and is integrated with the `objectiveML` and `objectiveGLS` objective functions; `optimizerSem`, written by Zhenghua Nie, is a modified version of the standard R `nlm` optimizer, which was written by Saikat DebRoy, R-core, and Richard H. Jones. The other functions call optimizers (`nlm`, `optim`, or `nlminb`), to fit structural equation models, and are called by the `sem` function. The user would not normally call these functions directly, but rather supply one of them in the `optimizer` argument to `sem`. Users may also write their own optimizer functions. `msemOptimizerNlm` is for fitting multigroup models, and also adapts the `nlm` code.

Usage

```
optimizerSem(start, objective=objectiveML,
             gradient=TRUE, maxiter, debug, par.size, model.description, warn, ...)
```

```
optimizerMsem(start, objective=msemObjectiveML, gradient=TRUE,
             maxiter, debug, par.size, model.description, warn=FALSE, ...)
```

```
optimizerNlm(start, objective=objectiveML, gradient=TRUE,
            maxiter, debug, par.size, model.description, warn, ...)
```

```
optimizerOptim(start, objective=objectiveML, gradient=TRUE,
              maxiter, debug, par.size, model.description, warn, method="CG", ...)
```

```
optimizerNlminb(start, objective=objectiveML, gradient=TRUE, maxiter,
               debug, par.size, model.description, warn, ...)
```

```
msemOptimizerNlm(start, objective=msemObjectiveML, gradient=TRUE,
                 maxiter, debug, par.size, model.description, warn=FALSE, ...)
```

Arguments

<code>start</code>	a vector of start values for the parameters.
<code>objective</code>	the objective function to be optimized; see objective.functions .
<code>gradient</code>	TRUE if an analytic gradient is to be used (if one is available).
<code>maxiter</code>	the maximum number of iterations allowed.
<code>debug</code>	TRUE to show the iteration history and other available information about the optimization.

par.size	"startvalues" to have the optimizer scale the problem according to the magnitudes of the start values (ignored by optimizerNlminb).
model.description	a list with elements describing the structural-equation model (see the code for details).
warn	if FALSE, suppress warnings during the optimization.
method	the method to be employed by the <code>optim</code> optimizer; the default is "CG" (conjugate-gradient).
...	additional arguments for the <code>nlm</code> , <code>optim</code> , or <code>nlminb</code> optimizer.

Value

An object of class "semResult", with elements:

convergence	TRUE if the optimization apparently converged.
iterations	the number of iterations required.
par	the vector of parameter estimates.
vcov	the estimated covariance matrix of the parameter estimates, based on a numeric Hessian; not supplied by <code>optimizerNlminb</code> .
criterion	the optimized value of the objective function.
C	the model-implied covariance or moment matrix at the parameter estimates.
A	the estimated A matrix.
P	the estimated P matrix.

pathDiagram

Draw Path Diagram

Description

pathDiagram creates a description of the path diagram for a structural-equation-model or SEM-specification object to be processed by the graph-drawing program *dot*.

Usage

```

pathDiagram(model, ...)

## S3 method for class 'sem'
pathDiagram(model, file = "pathDiagram",
  style = c("ram", "traditional"),
  output.type = c("html", "graphics", "dot"), graphics.fmt = "pdf",
  dot.options = NULL,
  size = c(8, 8), node.font = c("Helvetica", 14),
  edge.font = c("Helvetica", 10), digits = 2,
  rank.direction = c("LR", "TB"),
  min.rank = NULL, max.rank = NULL, same.rank = NULL,
  variables = model$var.names, var.labels, parameters, par.labels,
  ignore.double = TRUE, ignore.self = FALSE, error.nodes = TRUE,
  edge.labels = c("names", "values", "both"),
  edge.colors = c("black", "black"),
  edge.weight = c("fixed", "proportional"),
  node.colors = c("transparent", "transparent", "transparent"),
  standardize = FALSE, ...)

## S3 method for class 'semmod'
pathDiagram(model, obs.variables, ...)

math(text, html.only=FALSE, hat=FALSE)

```

Arguments

model	a structural-equation-model or SEM-specification object produced by <code>sem</code> , or, respectively, <code>specifyEquations</code> , <code>specifyModel</code> , or <code>cfa</code> .
...	arguments passed down, e.g., from the <code>semmod</code> method to the <code>sem</code> method.
file	a file name, by default "pathDiagram", given <i>without</i> an extension, to which to write the <i>dot</i> description of the path diagram if <code>output.type</code> "graphics" or "dot" is selected, and for the graphics output file (with appropriate extension) if "graphics" output is selected, in which case a ".dot" file and a graphics file of type specified by the <code>graphics.fmt</code> argument (below); file may include a path specification.
style	"ram" (the default) for a RAM path diagram including self-directed double-headed arrows representing variances, including error variances; or "traditional" for a path diagram including nodes representing error variables.
output.type	if "html" (the default), the path diagram will open in the user's default web browser; if "dot", a file containing <i>dot</i> commands will be written; if "graphics", both .dot and graphics files will be written.
graphics.fmt	a graphics format recognized by the <i>dot</i> program; the default is "pdf"; <code>graphics.fmt</code> is also used for the extension of the graphics file that is created.
dot.options	options to be passed to the <i>dot</i> program, given as a character string.
size	the size of the graph, in inches.

node.font	font name and point-size for printing variable names.
edge.font	font name and point-size for printing arrow names or values.
digits	number of digits after the decimal point (default, 2) to which to round parameter estimates.
rank.direction	draw graph left-to-right, "LR", the default, or top-to-bottom, "TB".
min.rank	a character string listing names of variables to be assigned minimum rank (order) in the graph; the names should be separated by commas.
max.rank	a character string listing names of variables to be assigned maximum rank in the graph; the names should be separated by commas.
same.rank	a character string or vector of character strings of variables to be assigned equivalent rank in the graph; names in each string should be separated by commas.
variables	variable names; defaults to the variable names in model. If specified, the variable names should be in the same order as in model.
var.labels	a character vector with labels to be used in lieu of (some of) the variables names, for greater flexibility in labelling nodes in the graph — e.g., the labels can be created with the math function. The elements of the vector must have names corresponding to variables in the model.
parameters	parameter names; defaults to the parameter names in model. If specified, the parameter names should be in the same order as in model.
par.labels	a character vector with labels to be used in lieu of (some of) the parameter names, for greater flexibility in labelling edges in the graph — e.g., the labels can be created with the math function. The elements of the vector must have names corresponding to parameters in the model.
ignore.double	if TRUE, the default, double-headed arrows, representing variances and covariances, are not graphed.
ignore.self	if TRUE (the default is FALSE), and ignore.double=FALSE, self-directed double-headed arrows representing error variances are suppressed; note that if ignore.double=TRUE, <i>all</i> double-headed arrows, including self-directed arrows, are suppressed.
error.nodes	if TRUE (the default) and style="traditional", show the nodes representing error variables.
edge.labels	"names" to label arrows with parameter names; "values" to label arrows with parameter estimates, or "both".
edge.colors	two-element character vector giving colors of positive and negative arrows respectively; the default is c("black", "black").
edge.weight	if "proportional" (the default is "fixed"), the thickness of edges is proportional to the absolute size of the corresponding parameter estimate; this is generally sensible only if standardize=TRUE.
node.colors	a two- or three-element character vector giving colors of nodes representing exogenous, endogenous, and error variables (for traditional path diagrams) consecutively; the default is "transparent" for all three; if a two colors are given, error variables are colored as exogenous (the first color).
standardize	if TRUE, display standardized coefficients; default is FALSE.
obs.variables	a character vector with the names of the observed variables in the model.

text	a character string or vector of character strings to be translated into node or edge label symbols. If a vector of character strings is supplied, then the elements of the vector should be named with the corresponding variable (node) or parameter (edge) name.
html.only	If TRUE (the default is FALSE), the character strings in text are to be treated as an HTML character codes, in which case the prefix "#" and suffix ";" are appended to each. Otherwise, text should only contain the names of lowercase or uppercase Greek letters, such as "alpha" or "Alpha". The full set of Greek letters recognized is given in the file Greek.txt in the package's etc subdirectory – or type <code>sem:::Greek</code> at the R command prompt. In either case, the symbols may be followed by numeric subscripts in curly braces consisting of numerals (e.g., "beta_{12}"), and/or numeric superscripts (e.g., "sigma^{2}", "sigma_{1}^{2}"). Superscripts and subscripts may also include most lowercase or uppercase letters. Depending upon your OS, subscripts and superscripts may only work properly with HTML output from pathDiagram, not with graphics output produced by <i>dot</i> .
hat	If TRUE (the default is FALSE), a hat (circumflex) is placed over the symbols in text; this feature doesn't produce a visually appealing result.

Details

pathDiagram creates a description of the path diagram for a structural-equation-model or SEM-specification object to be processed by the graph-drawing program *dot*, which can be called automatically; see Koutsofios and North (2002) and <https://www.graphviz.org/>. To obtain graphics output directly, the *dot* program must be on the system search path.

Alternatively, *HTML* output can be created in a web browser without an independent installation of *dot* using facilities in the **DiagrammeR** package.

The `math` function can be used to create node (variable) and edge (arrow) labels with symbols such as Greek letters, subscripts, and superscripts.

The `semmod` method of pathDiagram sets up a call to the `sem` method.

The various arguments to pathDiagram can be used to customize the diagram, but if there are too many constraints on node placement, *dot* may fail to produce a graph or may produce a distorted graph. pathDiagram can create both RAM-style diagrams, in which variances are represented as self-directed arrows, and traditional path diagrams, in which error variables appear explicitly as nodes. As is conventional, latent variables (including error variables) are represented as ellipses and observed variables as rectangles; double-headed arrows represent covariances (and in RAM diagrams, variances) and single-headed arrows represent structural coefficients.

Value

pathDiagram invisibly returns a character vector containing *dot* commands. `math` returns a character vector containing suitable HTML markup.

ram

RAM Matrix for a Structural-Equation Model

Description

Print the labelled RAM definition matrix for a structural-equation model fit by sem.

Usage

```
ram(object, digits=getOption("digits"), startvalues=FALSE)
```

Arguments

object	an object of class sem returned by the sem function.
digits	number of digits for printed output.
startvalues	if TRUE, start values for parameters are printed; otherwise, the parameter estimates are printed; the default is FALSE.

Value

A data frame containing the labelled RAM definition matrix, which is normally just printed.

Author(s)

John Fox <jfox@mcmaster.ca>

# ----- assumes that Duncan, Haller and Portes peer-influences model
# ----- has been fit and is in sem.dhp

## Not run:
ram(sem.dhp)

## End(Not run)
```

rawMoments

Compute Raw Moments Matrix

Description

Computes the “uncorrected” sum-of-squares-and-products matrix divided by the number of observations.

Usage

```
## S3 method for class 'formula'
rawMoments(formula, data, subset, na.action,
            contrasts=NULL, ...)

## Default S3 method:
rawMoments(object, na.rm=FALSE, ...)

cov2raw(cov, mean, N, sd)

## S3 method for class 'rawmoments'
print(x, ...)
```

Arguments

object	a one-sided model formula or an object coercible to a numeric matrix.
formula	a one-sided model formula specifying the model matrix for which raw moments are to be computed; note that a constant is included if it is not explicitly suppressed by putting -1 in the formula.
data	an optional data frame containing the variables in the formula. By default the variables are taken from the environment from which rawMoments is called.
subset	an optional vector specifying a subset of observations to be used in computing moments.
na.action	a function that indicates what should happen when the data contain NAs. The default is set by the na.action option.
contrasts	an optional list. See the contrasts.arg argument of model.matrix.default
.	
na.rm	if TRUE, any data rows with missing data will be removed.
cov	a covariance or correlation matrix.
mean	a vector of means.
N	the number of observations on which the covariances or correlations are based.
sd	an optional vector of standard deviations, to be given if cov is a correlation matrix.
x	an object of class rawmoments to print.
...	arguments passed down.

Value

rawMoments and cov2raw return an object of class rawmoments, which is simply a matrix with an attribute "N" that contains the number of observations on which the moments are based.

```

```
Cov <- with(Kmenta, cov(cbind(Q, P, D, F, A)))
cov2raw(Cov, colMeans(Kmenta), nrow(Kmenta))
```

`readMoments`*Input a Covariance, Correlation, or Raw Moment Matrix*

Description

This functions makes it simpler to input covariance, correlation, and raw-moment matrices to be analyzed by the [sem](#) function. The matrix is input in lower-triangular form on as many lines as is convenient, omitting the above-diagonal elements. The elements on the diagonal may also optionally be omitted, in which case they are taken to be 1.

Usage

```
readMoments(file="", text, diag=TRUE,  
            names=as.character(paste("X", 1:n, sep = "")))
```

Arguments

<code>file</code>	The (quoted) file from which to read the moment matrix, including the path to the file if it is not in the current directory. If "" (the default) and the text argument is absent, then the moment matrix is read from the standard input stream, and is terminated by a blank line.
<code>text</code>	The moment matrix given as a character string, as an alternative to specifying the file argument or reading the moments from the input stream — e.g., when the session is not interactive and there is no standard input.
<code>diag</code>	If TRUE (the default), then the input matrix includes diagonal elements.
<code>names</code>	a character vector containing the names of the variables, to label the rows and columns of the moment matrix.

Value

Returns a lower-triangular matrix (i.e., with zeroes above the main diagonal) suitable for input to `sem`.

residuals.sem

*Residual Covariances for a Structural Equation Model***Description**

These functions compute residual covariances, variance-standardized residual covariances, and normalized residual covariances for the observed variables in a structural-equation model fit by sem.

Usage

```

## S3 method for class 'sem'
residuals(object, ...)
## S3 method for class 'msem'
residuals(object, ...)

```

```
## S3 method for class 'sem'
standardizedResiduals(object, ...)
## S3 method for class 'msem'
standardizedResiduals(object, ...)

## S3 method for class 'objectiveML'
normalizedResiduals(object, ...)
## S3 method for class 'objectiveGLS'
normalizedResiduals(object, ...)
## S3 method for class 'msemObjectiveML'
normalizedResiduals(object, ...)
```

Arguments

`object` an object inheriting from class `sem` or `msem` returned by the `sem` function.
`...` not for the user.

Details

Residuals are defined as $S - C$, where S is the sample covariance matrix of the observed variables and C is the model-reproduced covariance matrix. The *standardized* residual covariance for a pair of variables divides the residual covariance by the product of the sample standard deviations of the two variables, $(s_{ij} - c_{ij}) / (s_{ii}s_{jj})^{1/2}$. The *normalized* residual is given by

$$\frac{s_{ij} - c_{ij}}{[(c_{ii}c_{jj} - c_{ij}^2)/N^*]^{1/2}}$$

where N^* is the number of observations minus one if the model is fit to a covariance matrix, or the number of observations if it is fit to a raw moment matrix.

Value

Each function returns a matrix of residuals.

sem

General Structural Equation Models

Description

sem fits general structural equation models (with both observed and unobserved variables). Observed variables are also called *indicators* or *manifest variables*; unobserved variables are also called *factors* or *latent variables*. Normally, the generic function (sem) is called directly with a semmod first argument produced by `specifyModel`, `specifyEquations`, or `cfa`, invoking the `sem.semmod` method, which in turn sets up a call to the `sem.default` method; thus, the user may wish to specify arguments accepted by the `semmod` and `default` methods. Similarly, for a multi-group model, `sem` would normally be called with a `semmodList` object produced by `multigroupModel` as its first argument, and would then generate a call to the `msemmod` method.

Usage

```

## S3 method for class 'semmod'
sem(model, S, N, data,
  raw=identical(na.action, na.pass), obs.variables=rownames(S),
  fixed.x=NULL, formula= ~ ., na.action=na.omit,
  robust=!missing(data), debug=FALSE,
  optimizer=optimizerSem, objective=objectiveML, ...)

## Default S3 method:
sem(model, S, N, raw=FALSE, data=NULL, start.fn=startvalues,
  pattern.number=NULL, valid.data.patterns=NULL,
  use.means=TRUE, param.names,
  var.names, fixed.x=NULL, robust=!is.null(data), semmod=NULL, debug=FALSE,
  analytic.gradient=!identical(objective, objectiveFIML),
  warn=FALSE, maxiter=1000, par.size=c("ones", "startvalues"),
  start.tol=1E-6, optimizer=optimizerSem, objective=objectiveML, cls, ...)

## S3 method for class 'semmodList'

```

```

sem(model, S, N, data, raw=FALSE, fixed.x=NULL,
     robust=!missing(data), formula, group="Group", debug=FALSE, ...)

## S3 method for class 'msemmod'
sem(model, S, N, start.fn=startvalues,
     group="Group", groups=names(model), raw=FALSE, fixed.x,
     param.names, var.names, debug=FALSE, analytic.gradient=TRUE, warn=FALSE,
     maxiter=5000, par.size = c("ones", "startvalues"), start.tol = 1e-06,
     start=c("initial.fit", "startvalues"), initial.maxiter=1000,
     optimizer = optimizerMsem, objective = msemObjectiveML, ...)

startvalues(S, ram, debug=FALSE, tol=1E-6)
startvalues2(S, ram, debug=FALSE, tol=1E-6)

## S3 method for class 'sem'
coef(object, standardized=FALSE, ...)
## S3 method for class 'msem'
coef(object, ...)
## S3 method for class 'sem'
vcov(object, robust=FALSE,
      analytic=inherits(object, "objectiveML") && object$t <= 500, ...)
## S3 method for class 'msem'
vcov(object, robust=FALSE,
      analytic=inherits(object, "msemObjectiveML") && object$t <= 500, ...)
## S3 method for class 'sem'
df.residual(object, ...)
## S3 method for class 'msem'
df.residual(object, ...)

```

Arguments

- | | |
|-------|--|
| model | RAM specification, which is a simple encoding of the path diagram for the model. The model may be given either in symbolic form (as a <code>semmod</code> object, as returned by the <code>specifyModel</code> , <code>specifyEquations</code> , or <code>cfa</code> function, or as a character matrix), invoking <code>sem.semmod</code> , which calls <code>sem.default</code> after setting up the model, or (less conveniently) in numeric form, invoking <code>sem.default</code> directly, which is not recommended (see Details below). The <code>model</code> argument may also be a multigroup-model specification, as produced by <code>multigroupModel</code> . |
| S | covariance matrix among observed variables; may be input as a symmetric matrix, or as a lower- or upper-triangular matrix. <code>S</code> may also be a raw (i.e., “uncorrected”) moment matrix — that is, a sum-of-squares-and-products matrix divided by <code>N</code> . This form of input is useful for fitting models with intercepts, in which case the moment matrix should include the mean square and cross-products for a unit variable all of whose entries are 1; of course, the raw mean square for the unit variable is 1. Raw-moment matrices may be computed by <code>rawMoments</code> . If the <code>ram</code> argument is given in symbolic form, then the observed-variable covariance or raw-moment matrix may contain variables that do not appear in the model, in which case a warning is printed. <code>S</code> may also be a list |

	of covariance or moment matrices for each group in a multigroup model. As an alternative to specifying <code>S</code> the user may supply a data frame containing the data for the model (see the argument <code>data</code>).
<code>N</code>	number of observations on which the covariance matrix is based; for a multigroup model, a vector of group N s.
<code>data</code>	As a generally preferable alternative to specifying <code>S</code> and <code>N</code> , the user may supply a data frame containing the data to which the model is to be fit. In a multigroup model, the <code>data</code> argument may be a list of data frames or a single data frame; in the later event, the factor given as the <code>group</code> argument is used to split the data into groups.
<code>start.fn</code>	a function to compute startvalues for the free parameters of the model; two functions are supplied, <code>startvalues</code> and a older version, <code>startvalues2</code> , the first of which is the default.
<code>na.action</code>	a function to process missing data, if raw data are supplied in the <code>data</code> argument. The default is <code>na.omit</code> , which returns only complete cases; specify <code>na.action=na.pass</code> to get FIML estimates in the presence of missing data from the <code>objectiveFIML</code> and <code>objectiveFIML2</code> objective functions.
<code>raw</code>	TRUE if <code>S</code> is a raw moment matrix or if a raw moment matrix — as opposed to a covariance matrix — is to be computed from data; the default is FALSE unless the <code>na.action</code> argument is set to <code>na.pass</code> .
<code>pattern.number</code> , <code>valid.data.patterns</code>	these arguments pass information about valid (i.e., non-missing) data patterns and normally would not be specified directly by the user.
<code>use.means</code>	When raw data are supplied and intercepts are included in the model, use the observed-variable means as start values for the intercepts; the default is TRUE.
<code>obs.variables</code>	names of observed variables, by default taken from the row names of the covariance or moment matrix <code>S</code> , which may be given directly or generated according to the <code>data</code> and <code>formula</code> arguments.
<code>fixed.x</code>	names (if the <code>ram</code> matrix is given in symbolic form) or indices (if it is in numeric form) of fixed exogenous variables. Specifying these obviates the necessity of having to fix the variances and covariances among these variables (and produces correct degrees of freedom for the model <code>chisquare</code>).
<code>formula</code>	a one-sided formula, to be applied to data to generate the variables for which covariances or raw moments are computed. The default formula is <code>~.</code> , i.e., all of the variables in the data, including an implied intercept; if a covariance matrix is to be computed, the constant is suppressed. In a multigroup model, alternatively a list one one-sided formulas as be given, to be applied individually to the groups.
<code>robust</code>	In <code>sem</code> : if TRUE, then quantities are calculated that can be used to compute robust estimates of coefficient standard errors and robust tests when the model is fit by multinormal maximum likelihood; the default is TRUE when the <code>data</code> argument is TRUE, and this option is only available when the <code>data</code> argument is given. In <code>vcov</code> : if TRUE, return a robust coefficient covariance matrix (if object contains the requisite information).
<code>semmod</code>	a <code>semmod</code> object containing the description of the model; optional, and normally supplied not directly by the user but via the <code>semmod</code> method for <code>sem</code> .

<code>debug</code>	if TRUE, some information is printed to help you debug the symbolic model specification; for example, if a variable name is misspelled, <code>sem</code> will assume that the variable is a (new) latent variable. Information about the optimization will also be printed, but details will vary with the optimizer employed. The default is FALSE.
<code>...</code>	arguments to be passed down, including from <code>sem.default</code> to the optimizer.
<code>param.names</code>	names of the t free parameters, given in their numerical order; default names are <code>Param1, ..., Paramt</code> . Note: Should not be specified when the model is given in symbolic form.
<code>var.names</code>	names of the m entries of the v vector (typically the observed and latent variables — see below), given in their numerical order; default names are <code>Var1, ..., Varm</code> . Note: Should not be specified when the model is given in symbolic form.
<code>analytic.gradient</code>	if TRUE (the default, except for the <code>objectiveFIML</code> objective function, where, at present, an analytic gradient slows down the computation), then analytic first derivatives are used in the maximization of the likelihood if the optimizer employed will accept them; otherwise numeric derivatives are used, again if the optimizer will compute them.
<code>warn</code>	if TRUE, warnings produced by the optimization function will be printed. This should generally not be necessary, since <code>sem</code> prints its own warning, and saves information about convergence. The default is FALSE.
<code>maxiter</code>	the maximum number of iterations for the optimization of the objective function, to be passed to the optimizer.
<code>par.size</code>	the anticipated size of the free parameters; if "ones", a vector of ones is used; if "startvalues", taken from the start values. You can try changing this argument if you encounter convergence problems. The default is "startvalues" if the largest input variance is at least 100 times the smallest, and "ones" otherwise. Whether this argument is actually used depends upon the optimizer employed.
<code>start.tol, tol</code>	if the magnitude of an automatic start value is less than <code>start.tol</code> , then it is set to <code>start.tol</code> ; defaults to 1E-6.
<code>optimizer</code>	a function to be used to minimize the objective function; the default for single-group models is <code>optimizerSem</code> . Alternatives are <code>nlm</code> , which employs the standard R optimizer <code>nlm</code> ; <code>optimizerOptim</code> , which employs <code>optim</code> ; and <code>optimizerNlminb</code> , which uses <code>nlminb</code> — or the user can supply an optimizer. For multigroup model, the default is <code>optimizerMsem</code> , and <code>msemOptimizerNlm</code> , based on <code>nlm</code> , is provided as an alternative.
<code>objective</code>	An objective function to be minimized, sometimes called a "fit" function in the SEM literature. The default for single-group models is <code>objectiveML</code> , which produces maximum-likelihood estimates assuming multinormality. An alternative is <code>objectiveGLS</code> , which produced generalized least squares estimates — or the user can supply an objective function to be minimized. For multigroup models, the default is available is <code>msemObjectiveML</code> for ML estimates and an alternative is <code>msemObjectiveGLS</code> for GLS estimates.
<code>cls</code>	primary class to be assigned to the result; normally this is not specified directly, but rather is inferred from the objective function.

<code>ram</code>	numeric RAM matrix.
<code>object</code>	an object of class "sem" or "msem", returned by <code>sem</code> .
<code>standardized</code>	if TRUE, return standardized coefficients.
<code>analytic</code>	return an analytic (as opposed to numeric) estimate of the coefficient covariance matrix; at present only available for the <code>objectiveML</code> objective function. The default is FALSE for this objective function if there are no more than 100 parameters and FALSE otherwise.
<code>group</code>	for a multigroup model, the quoted name of the group variable; if the data argument is given, and is a single data frame, then this should be a factor in the data set or a variable coercible to a factor, to be used to split the data into groups; otherwise, the name is arbitrary.
<code>groups</code>	a character vector giving the names of the groups; will be ignored if <code>group</code> is a factor in data.
<code>start</code>	if "initial.fit" (the default), start values for a multi-group model are computed by first fitting the intra-group models separately by group; if "startvalues", then start values are computed as for a single-group model. In some cases, the intra-group models may not be identified even if the multi-group model is, and then <code>start="initial.fit"</code> should not be used.
<code>initial.maxiter</code>	if <code>start="initial.fit"</code> for a multi-group model, then <code>initial.maxiter</code> gives the maximum number of iterations for each initial intra-group fit.

Details

The model is set up using either RAM (“reticular action model” – don’t ask!) notation – a simple format for specifying general structural equation models by coding the “arrows” in the path diagram for the model (see, e.g., McArdle and McDonald, 1984) – typically using the `specifyModel` function; in equation format using the `specifyEquations` function; or, for a simple confirmatory factor analysis model, via the `cfa` function. In any case, the model is represented internally in RAM format.

The variables in the v vector in the model (typically, the observed and unobserved variables, but not error variables) are numbered from 1 to m . the RAM matrix contains one row for each (free or constrained) parameter of the model, and may be specified either in symbolic format or in numeric format.

A symbolic `ram` matrix consists of three columns, as follows:

- 1. Arrow specification:** This is a simple formula, of the form "A -> B" or, equivalently, "B <- A" for a regression coefficient (i.e., a single-headed or directional arrow); "A <-> A" for a variance or "A <-> B" for a covariance (i.e., a double-headed or bidirectional arrow). Here, A and B are variable names in the model. If a name does not correspond to an observed variable, then it is assumed to be a latent variable. Spaces can appear freely in an arrow specification, and there can be any number of hyphens in the arrows, including zero: Thus, e.g., "A->B", "A --> B", and "A>B" are all legitimate and equivalent.
- 2. Parameter name:** The name of the regression coefficient, variance, or covariance specified by the arrow. Assigning the same name to two or more arrows results in an equality constraint. Specifying the parameter name as NA produces a fixed parameter.

3. Value: start value for a free parameter or value of a fixed parameter. If given as NA, sem will compute the start value.

It is simplest to construct the RAM matrix with the `specifyModel`, `specifyEquations`, or `cfa` function, all of which return an object of class `semmod`, and also incorporate some model-specification convenience shortcuts. This process is illustrated in the examples below.

A numeric ram matrix consists of five columns, as follows:

- 1. Number of arrow heads:** 1 (directed arrow) or 2 (covariance).
- 2. Arrow to:** index of the variable at the head of a directional arrow, or at one end of a bidirectional arrow. Observed variables should be assigned the numbers 1 to n , where n is the number of rows/columns in the covariance matrix S , with the indices corresponding to the variables' positions in S . Variable indices above n represent latent variables.
- 3. Arrow from:** the index of the variable at the tail of a directional arrow, or at the other end of a bidirectional arrow.
- 4. Parameter number:** free parameters are numbered from 1 to t , but do not necessarily appear in consecutive order. Fixed parameters are given the number 0. Equality constraints are specified by assigning two or more parameters the same number.
- 5. Value:** start value for a free parameter, or value of a fixed parameter. If given as NA, the program will compute a start value, by a slight modification of the method described by McDonald and Hartmann (1992). *Note:* In some circumstances, some start values are selected randomly; this might produce small differences in the parameter estimates when the program is rerun.

The numeric ram matrix is normally generated automatically, not specified directly by the user.

For `specifyEquations`, each input line is either a regression equation or the specification of a variance or covariance. Regression equations are of the form

$$y = \text{par1} * x_1 + \text{par2} * x_2 + \dots + \text{park} * x_k$$

where y and the x s are variables in the model (either observed or latent), and the pars are parameters. If a parameter is given as a numeric value (e.g., 1) then it is treated as fixed. Note that no “error” variable is included in the equation; “error variances” are specified via either the `covs` argument, via $V(y) = \text{par}$ (see immediately below), or are added automatically to the model when, as by default, `endog.variances=TRUE`.

Variances are specified in the form $V(\text{var}) = \text{par}$ and covariances in the form $C(\text{var1}, \text{var2}) = \text{par}$, where the vars are variables (observed or unobserved) in the model. The symbols V and C may be in either lower- or upper-case. If par is a numeric value (e.g., 1) then it is treated as fixed. In conformity with the RAM model, a variance or covariance for an endogenous variable in the model is an “error” variance or covariance.

To set a start value for a free parameter, enclose the numeric start value in parentheses after the parameter name, as `parameter(value)`.

`sem` fits the model by calling the optimizer specified in the `optimizer` argument to minimize the objective function specified in the `objective` argument. If the optimization fails to converge, a warning message is printed.

The RAM formulation of the general structural equation model is given by the basic equation

$$v = Av + u$$

where v and u are vectors of random variables (observed or unobserved), and the parameter matrix A contains regression coefficients, symbolized by single-headed arrows in a path diagram. Another parameter matrix,

$$P = E(uu')$$

contains covariances among the elements of u (assuming that the elements of u have zero means). Usually v contains endogenous and exogenous observed and unobserved variables, but not error variables (see the examples below).

The `startvalues` function may be called directly, but is usually called by `sem.default`; `startvalues2` is an older version of this function that may be used alternatively; see the `startvalues` argument to `sem`.

Value

`sem` returns an object of class `c(objective, "sem")`, where *objective* is the name of the objective function that was optimized (e.g., "objectiveML"), with the following elements:

<code>var.names</code>	vector of variable names.
<code>ram</code>	RAM matrix, including any rows generated for covariances among fixed exogenous variables; column 5 includes computed start values.
<code>S</code>	observed covariance matrix.
<code>J</code>	RAM selection matrix, J , which picks out observed variables.
<code>n.fix</code>	number of fixed exogenous variables.
<code>n</code>	number of observed variables.
<code>N</code>	number of observations.
<code>m</code>	number of variables (observed plus unobserved).
<code>t</code>	number of free parameters.
<code>raw</code>	TRUE if the model is fit to a raw moment matrix, FALSE otherwise.
<code>data</code>	the observed-variable data matrix, or NULL if data are not supplied.
<code>semmod</code>	the <code>semmod</code> specification object for the model, if one was supplied; otherwise NULL.
<code>optimizer</code>	the optimizer function.
<code>objective</code>	the objective function.
<code>coeff</code>	estimates of free parameters.
<code>vcov</code>	estimated asymptotic covariance matrix of parameter estimates, based on a numeric Hessian, if supplied by the optimizer; otherwise NULL.
<code>par.posn</code>	indices of free parameters.
<code>convergence</code>	TRUE or FALSE, depending upon whether the optimization apparently converged.
<code>iterations</code>	number of iterations performed.
<code>criterion</code>	value of the objective function at the minimum.
<code>C</code>	model-reproduced covariance matrix.
<code>A</code>	RAM A matrix.

P RAM P matrix.
 adj.obj robust adjusted value of the objective function; NULL if robust is FALSE.
 robust.vcov robust estimated coefficient covariance matrix; NULL if robust is FALSE.

For multigroup models, sem returns an object of class `c("msemObjectiveML", "msem")`.

Warning

A common error is to fail to specify variance or covariance terms in the model, which are denoted by double-headed arrows, `<->`.

In general, every observed or latent variable in the model should be associated with a variance or error variance. This may be a free parameter to estimate or a fixed constant (as in the case of a latent exogenous variable for which you wish to fix the variance, e.g., to 1). Again in general, there will be an *error variance* associated with each endogenous variable in the model (i.e., each variable to which at least one single-headed arrow points — including observed indicators of latent variables), and a *variance* associated with each exogenous variable (i.e., each variable that appears only at the tail of single-headed arrows, never at the head).

To my knowledge, the only *apparent* exception to this rule is for observed variables that are declared to be fixed exogenous variables. In this case, the program generates the necessary (fixed-constant) variances and covariances automatically.

If there are missing variances, a warning message will be printed, and estimation will almost surely fail in some manner. Missing variances might well indicate that there are missing covariances too, but it is not possible to deduce this in a mechanical manner. The `specifyModel` function will by default supply error-variance parameters if these are missing.

sem-deprecated

Deprecated Functions in the sem Package

Description

These functions are provided for compatibility with older versions of the **sem** package only, and may be removed eventually. Although an effort has been made to insure backwards-compatibility, commands that worked in versions of the **sem** package prior to version 2.0-0 will not necessarily work in version 2.0-0 and beyond, or may not work in the same manner.

Usage

```

boot.sem(...)
mod.indices(...)
normalized.residuals(...)
path.diagram(...)
raw.moments(...)
read.moments(...)
specify.model(...)
standardized.coefficients(...)
standardized.residuals(...)
std.coef(...)

```

Arguments

... pass arguments down to replacements for deprecated functions.

Details

`boot.sem` is now a synonym for the `bootSem` function.

`mod.indices` is now a synonym for `modIndices`.

`normalized.residuals` is now a synonym for `normalizedResiduals`.

`path.diagram` is now a synonym for `pathDiagram`.

`raw.moments` is now a synonym for `rawMoments`.

read.moments is now a synonym for [readMoments](#).

specify.model is now a synonym for [specifyModel](#).

standardized.coefficients and std.coef are now synonyms for the [standardizedCoefficients](#) and [stdCoef](#) functions.

standardized.residuals is now a synonym for [standardizedResiduals](#).

specifyModel	<i>Specify a Structural Equation Model</i>
--------------	--

Description

Create the RAM specification of a structural equation model.

Usage

```
specifyModel(file="", text, exog.variances=FALSE, endog.variances=TRUE, covs,
             suffix="", quiet=FALSE)
```

```
specifyEquations(file="", text, ...)
```

```
cfa(file="", text, covs=paste(factors, collapse=","),
    reference.indicators=TRUE, raw=FALSE,
    subscript=c("name", "number"), ...)
```

```
multigroupModel(..., groups=names(models), allEqual=FALSE)
```

```
classifyVariables(model)
```

```
removeRedundantPaths(model, warn=TRUE)
## S3 method for class 'semmod'
combineModels(..., warn=TRUE)
## S3 method for class 'semmod'
update(object, file = "", text, ...)
## S3 method for class 'semmod'
edit(name, ...)
```

```
## S3 method for class 'semmod'
print(x, ...)
## S3 method for class 'semmodList'
print(x, ...)
```

Arguments

file	The (quoted) file from which to read the model specification, including the path to the file if it is not in the current directory. If "" (the default) and the text argument is not supplied, then the specification is read from the standard input stream, and is terminated by a blank line.
------	--

text	The model specification given as a character string, as an alternative to specifying the <code>Jfile</code> argument or reading the model specification from the input stream — e.g., when the session is not interactive and there is no standard input.
exog.variances	If TRUE (the default is FALSE), free variance parameters are added for the exogenous variables that lack them.
endog.variances	If TRUE (the default), free error-variance parameters are added for the endogenous variables that lack them.
covs	optional: a character vector of one or more elements, with each element giving a string of variable names, separated by commas. Variances and covariances among all variables in each such string are added to the model. For confirmatory factor analysis models specified via <code>cfa</code> , <code>covs</code> defaults to all of the factors in the model, thus specifying all variances and covariances among these factors. <i>Warning:</i> <code>covs="x1, x2"</code> and <code>covs=c("x1", "x2")</code> are <i>not</i> equivalent: <code>covs="x1, x2"</code> specifies the variance of <code>x1</code> , the variance of <code>x2</code> , <i>and</i> their covariance, while <code>covs=c("x1", "x2")</code> specifies the variance of <code>x1</code> and the variance of <code>x2</code> <i>but not</i> their covariance.
suffix	a character string (defaulting to an empty string) to be appended to each parameter name; this can be convenient for specifying multiple-group models.
reference.indicators	if FALSE, the default, variances of factors are set to 1 by <code>cfa</code> ; if TRUE, variances of factors are free parameters to estimate from the data, and instead the first factor loading for each factor is set to 1 to identify the model.
raw	if TRUE (the default is FALSE), a path from Intercept to each observed variable is added to the model, and the raw second moment for Intercept is fixed to 1. The <code>sem</code> function should then be called with <code>raw=TRUE</code> , and either supplied with a data set (via the <code>data</code> argument) or a raw-moment matrix (via the <code>S</code> argument).
subscript	The “subscripts” to be appended to <code>lam</code> to name factor-loading parameters, either “name” (the default) to use the names of observed variables, or “number” to number the parameters serially within each factor. Using “number” produces shorter parameter names.
quiet	if FALSE, the default, then the number of input lines is reported and a message is printed suggesting that <code>specifyEquations</code> or <code>cfa</code> be used.
x, model, object, name	An object of class <code>semmod</code> or <code>semmodList</code> , as produced by <code>specifyModel</code> or <code>multigroupModel</code> .
warn	print a warning if redundant paths are detected.
...	For <code>multigroupModel</code> , one or more optionally named arguments each of which is a <code>semmod</code> object produced, e.g., by <code>specifyModel</code> , <code>specifyEquations</code> , or <code>cfa</code> ; if only one such model is given, then it will be used for all groups defined by the <code>groups</code> argument. If parameters have the same name in different groups, then they will be constrained to be equal. For <code>specifyEquations</code> and <code>cfa</code> , arguments (such as <code>covs</code> , in the case of <code>specifyEquations</code>) to be passed to <code>specifyModel</code> ; for <code>combineModels</code> , <code>sem</code> objects; ignored in the <code>update</code> and <code>print</code> methods.

groups	a character vector of names for the groups in a multigroup model; taken by default from the names of the . . . arguments.
allEqual	if FALSE (the default), then if only one model object is given for a multigroup model, all corresponding parameters in the groups will be distinct; if TRUE, all corresponding parameters will be constrained to be equal.

Details

The principal functions for model specification are `specifyModel`, to specify a model in RAM (path) format via single- and double-headed arrows; `specifyEquations`, to specify a model in equation format, which is then translated by the function into RAM format; and `cfa`, for compact specification of simple confirmatory factor analysis models.

`specifyModel`:

Each line of the RAM specification for `specifyModel` consists of three (unquoted) entries, separated by commas:

- 1. Arrow specification:** This is a simple formula, of the form $A \rightarrow B$ or, equivalently, $B \leftarrow A$ for a regression coefficient (i.e., a single-headed or directional arrow); $A \leftrightarrow A$ for a variance or $A \leftrightarrow B$ for a covariance (i.e., a double-headed or bidirectional arrow). Here, A and B are variable names in the model. If a name does not correspond to an observed variable, then it is assumed to be a latent variable. Spaces can appear freely in an arrow specification, and there can be any number of hyphens in the arrows, including zero: Thus, e.g., $A \rightarrow B$, $A \dashrightarrow B$, and $A > B$ are all legitimate and equivalent.
- 2. Parameter name:** The name of the regression coefficient, variance, or covariance specified by the arrow. Assigning the same name to two or more arrows results in an equality constraint. Specifying the parameter name as NA produces a fixed parameter.
- 3. Value:** start value for a free parameter or value of a fixed parameter. If given as NA (or simply omitted), `sem` will compute the start value.

Lines may end in a comment following #.

`specifyEquations`:

For `specifyEquations`, each input line is either a regression equation or the specification of a variance or covariance. Regression equations are of the form

$$y = \text{par1} * x_1 + \text{par2} * x_2 + \dots + \text{park} * x_k$$

where y and the xs are variables in the model (either observed or latent), and the pars are parameters. If a parameter is given as a numeric value (e.g., 1) then it is treated as fixed. Note that no “error” variable is included in the equation; “error variances” are specified via either the `covs` argument, via $V(y) = \text{par}$ (see immediately below), or are added automatically to the model when, as by default, `endog.variances=TRUE`. A regression equation may be split over more than one input by breaking at a +, so that + is either the last non-blank character on a line or the first non-blank character on the subsequent line.

Variances are specified in the form $V(\text{var}) = \text{par}$ and covariances in the form $C(\text{var1}, \text{var2}) = \text{par}$, where the vars are variables (observed or unobserved) in the model. The symbols V and C may be in either lower- or upper-case. If par is a numeric value (e.g., 1) then it is treated as fixed. In conformity with the RAM model, a variance or covariance for an endogenous variable in the model is an “error” variance or covariance.

Warning: If the `covs` argument to `specifyEquations` is used to specify variances and covariances, please be aware that `covs="x1, x2"` and `covs=c("x1", "x2")` are *not* equivalent: `covs="x1, x2"` specifies the variance of `x1`, the variance of `x2`, *and* their covariance, while `covs=c("x1", "x2")` specifies the variance of `x1` and the variance of `x2` *but not* their covariance.

To set a start value for a free parameter, enclose the numeric start value in parentheses after the parameter name, as `parameter(value)`.

`cfa`:

For `cfa`, each input line includes the names of the variables, separated by commas, that load on the corresponding factor; the name of the factor is given optionally at the beginning of the line, followed by a colon. If necessary, the variables that load on a factor may be continued across two or more input lines; in this case, each such line but the last must end in a comma. A variable may load on more than one factor (as long as the resulting model is identified, of course), but each factor may appear in only one input line (or set of input lines, if the variable list is continued onto the next line).

Equality constraints for factor loadings can be set by using equal-signs (=) rather than commas to separate observed variable names. For example, `fac1: x1=x2=x3, x4=x5` sets the loadings for `x1`, `x2`, and `x3` equal to each other, and the loadings for `x4` and `x5` equal to each other.

Equality constraints among error variances can similarly be specified by using `var:` or `variance:` at the beginning of a line (actually, any character string beginning with `var` will do, and thus no factor name may begin with the characters `var`). For example, `var: x1=x2=x3, x4=x5` sets the error variances for `x1`, `x2`, and `x3` equal to each other, and the error variances for `x4` and `x5` equal to each other. There may be several lines beginning with `var:`.

If the argument `reference.indicators=FALSE`, the default, `cfa` will fix the variance of each factor to 1, and by default include covariances (i.e., correlations) among all pairs of factors. Alternatively, if `reference.indicators=TRUE`, then the factor variances are free parameters to be estimated from the data, and the first loading for each factor is set to 1 to identify the model. These two approaches produce equivalent models, with the same fit to the data, but alternative parametrizations. Specifying the argument `covs=NULL` implicitly fixes the factor intercorrelations to 0.

See [sem](#) and the examples for further details on model specification.

Other Functions:

`classifyVariables` classifies the variables in a model as endogenous or exogenous.

`combineModels` and `removeRedundantPaths` take `semmod` objects as arguments and do what their names imply.

The file input argument to the update method for `semmod` objects, which by default comes from standard input, is a set of update directives, one per line. There are five kinds of directives. In each case the directive begins with the directive name, followed by one or more fields separated by commas.

- 1. delete:** Remove a path from the model. Example: `delete, RSES -> FGenAsp`
- 2. add:** Add a path to the model. Example (the NA for the start value is optional): `add, RSES -> FGenAsp, gam14, NA`
- 3. replace:** Replace every occurrence of the first string with the second in the variables and parameters of the model. This directive may be used, for example, to change one variable to another or to rename a parameter. Example: `replace, gam, gamma`, substitutes the string "gamma" for "gam" wherever the latter appears, presumably in parameter names.

4. **fix:** Fix a parameter that was formerly free. Example: `fix, RGenAsp -> REdAsp, 1`
5. **free:** Free a parameter that was formerly fixed. Example (the NA for the start value is optional): `free, RGenAsp -> ROccAsp, lam11, NA`

The `edit` method for `semmod` objects opens the model in the R editor.

Value

`specifyModel`, `specifyEquations`, `cfa`, `removeRedundantPaths`, `combineModels`, `update`, and `edit` return an object of class `semmod`, suitable as input for [sem](#).

`multigroupModel` returns an object of class `semmodList`, also suitable as input for [sem](#).

`classifyVariables` returns a list with two character vectors: `endogenous`, containing the names of endogenous variables in the model; and `exogenous`, containing the names of exogenous variables.

standardizedCoefficients

Standardized Coefficients for Structural Equation Models

Description

These functions calculate standardized regression coefficients for structural equation models. The function `stdCoef` is simply an abbreviation for `standardizedCoefficients`.

Usage

```

standardizedCoefficients(object, ...)
## S3 method for class 'sem'
standardizedCoefficients(object,
                          digits = getOption("digits"), oneheaded = TRUE, twoheaded = TRUE, ...)
## S3 method for class 'msem'
standardizedCoefficients(object, ...)

stdCoef(...)

```

Arguments

object	an object of class <code>sem</code> or <code>msem</code> returned by the <code>sem</code> function.
digits	number of digits for printed output.
oneheaded	standardize path coefficients? Default is TRUE.
twoheaded	standardize variances and covariances? Default is TRUE.
...	arguments to pass down.

Value

Returns a data frame with the coefficients, labelled both by parameter names and by arrows in the path diagram for the model. The `msem` (multigroup) method computes and prints the standardized coefficients for each group; it does not return a useful result.

Tests

Six Mental Tests

Description

These data are from the SAS manual and consist of six mental tests for 32 students, with some missing data. The three x variables are intended to load on a verbal factor, and the three y variables on a math factor. The data can be used to illustrate the estimation of a confirmatory factor analysis model by multinormal full-information maximum-likelihood in the presence of missing data.

Usage

Tests

Format

A data frame with 32 observations on the following 6 variables.

x1 score on verbal test 1.
 x2 score on verbal test 2.
 x3 score on verbal test 3.
 y1 score on math test 1.
 y2 score on math test 2.
 y3 score on math test 3.

tsls	<i>Two-Stage Least Squares</i>
------	--------------------------------

Description

Fits a regression equation, such as an equation in a structural-equation model, by two-stage least squares. This is equivalent to direct instrumental-variables estimation when the number of instruments is equal to the number of predictors.

Usage

```
## S3 method for class 'formula'
tsls(formula, instruments, data, subset, weights,
     na.action, contrasts=NULL, ...)
## Default S3 method:
tsls(y, X, Z, w, names=NULL, ...)

## S3 method for class 'tsls'
print(x, ...)
## S3 method for class 'tsls'
summary(object, digits=getOption("digits"), ...)
## S3 method for class 'summary.tsls'
print(x, ...)
## S3 method for class 'tsls'
anova(object, model.2, s2, dfe, ...)

## S3 method for class 'tsls'
fitted(object, ...)
## S3 method for class 'tsls'
residuals(object, ...)
## S3 method for class 'tsls'
coef(object, ...)
## S3 method for class 'tsls'
vcov(object, ...)
```

Arguments

formula	model formula for structural equation to be estimated; a regression constant is implied if not explicitly omitted.
instruments	one-sided model formula specifying instrumental variables.
data	an optional data frame containing the variables in the model. By default the variables are taken from the environment from which <code>tsls</code> is called.
subset	an optional vector specifying a subset of observations to be used in fitting the model.
weights, w	an optional vector of weights to be used in the fitting process; if specified should be a non-negative numeric vector with one entry for each observation, to be used to compute weighted 2SLS estimates.
na.action	a function that indicates what should happen when the data contain NAs. The default is set by the <code>na.action</code> option.
contrasts	an optional list. See the <code>contrasts.arg</code> argument of <code>model.matrix.default</code> .
y	Response-variable vector.
X	Matrix of predictors, including a constant (if one is in the model).
Z	Matrix of instrumental variables, including a constant (if one is in the model).
names	optional character vector of names for the columns of the X matrix.
x, object, model.2	objects of class <code>tsls</code> returned by <code>tsls.formula</code> (or of class <code>summary.tsls</code>), for anova containing nested models to be compared by an incremental F -test. One model should be nested in the other; the order of models is immaterial.
s2	an optional estimate of error variance for the denominator of the F -test. If missing, the error-variance estimate is taken from the larger model.
dfe	optional error degrees of freedom, to be specified when an estimate of error variance is given.
digits	number of digits for summary output.
...	arguments to be passed down.

Value

`tsls.formula` returns an object of class `tsls`, with the following components:

n	number of observations.
p	number of parameters.
coefficients	parameter estimates.
V	estimated covariance matrix of coefficients.
s	residual standard error.
residuals	vector of residuals.
response	vector of response values.
X	model matrix.

Z instrumental-variables matrix.
response.name name of response variable, or expression evaluating to response.
formula model formula.
instruments one-sided formula for instrumental variables.
